

CORE WORKFLOW

How Cleanones Runs

The operational core, end to end: clients, sites, checklists, schedules, crews, and the daily shift itself.

Scope – client setup, scheduling, worker assignment, shift lifecycle, ad-hoc tasks, manager oversight

Prepared – September 2026

Contents

00	System at a glance	The five building blocks, in one picture
01	Who runs it	Manager, Worker, Client
02	Setting up a client	Client → Location → Room → Task
03	Building the schedule	Cleaning Plans, recurrence, worker assignment
04	The shift lifecycle	Recurring, creating, checking in, working, checking out
05	Ad-hoc task requests	Work outside the regular schedule
06	Manager oversight & roster	Dashboards, attendance, the full roster

System at a glance

The entire system is built from five nested building blocks, and everything else in this document is really about how those blocks connect on a daily basis.

A **Client** owns one or more **Locations**. Each Location is broken into **Rooms**. Each Room carries a set of recurring **Tasks** — the checklist. A **Cleaning Plan** ties a client, a location, a set of rooms, and a crew of workers together on a schedule. Every day that schedule is due, the system generates a dated **Shift** — a frozen, on-the-record copy of that plan for that day — which is what a worker actually checks into and works through.

The five building blocks: a Client's Location is divided into Rooms, each carrying recurring Tasks. A Cleaning Plan bundles a location, its rooms and its crew, and produces one dated Shift for every day it's due.

Three roles carry the entire operational flow described in this document.

Manager

Runs day-to-day operations: onboards clients, builds locations, rooms and schedules, assigns crews, reviews progress, adjusts as needed.

Worker

Performs the cleaning. Checks in and out on site, works through the room-by-room checklist, submits proof of completed work.

Client

Owns the property. Sees their own schedule and live progress in real time — read-only over the operational data.

Setting up a client

Every new customer relationship is built in the same order, and always starts with a Manager — clients never set themselves up.

1 Manager creates the Client account

Name, company and contact details are recorded, and login access is issued to the client.

MANAGER

2 Manager adds one or more Locations

Each Location is a physical site — a Hotel, School, Hospital, Office, or Other type — with a street address *and* a precise GPS coordinate. That coordinate is what every future worker check-in is measured against.

MANAGER

3 Manager adds Rooms under each Location

A site is broken into its individual rooms, floors, and room/cleaning types — the units that work actually gets tracked against.

MANAGER

4 Manager defines Tasks for each Room

What has to be done, how often it repeats, roughly how long it takes, and whether the worker must submit photo proof to close it out.

MANAGER

5 Client sees their own portal

From this point the client can view their own locations, rooms, schedule and live progress — never another client's data, and never able to edit it.

CLIENT · READ-ONLY

Moving a Location's pin later automatically updates today's not-yet-started shift too, so a corrected address is enforced immediately rather than waiting for the next day.

A Cleaning Plan is the contract: this client, this location, these rooms, this crew, starting on this date (and optionally ending on one).

The recurrence itself — how often the work repeats — lives one level down, on the Tasks. Because each Task carries its own frequency, a single plan can quietly mix cadences: bathrooms cleaned daily, carpets vacuumed every Tuesday and Friday, a deep-clean of the lobby on the 1st of the month — all under one plan, one crew, one client. The plan is "due" on any day where at least one of its tasks is scheduled to run.

Assigning the crew

When a Manager assigns a worker to a plan, two independent checks run automatically:

- **Eligibility** — hard, never overridable. The worker's account must be active. If it isn't, the assignment is refused outright.
- **Scheduling conflict** — a warning, not a block. The system checks whether the worker is already committed elsewhere at an overlapping time and date. If so, the Manager sees exactly which other plan conflicts, and can either choose someone else or force the assignment through — which is then permanently marked on the record as a deliberate override, never a silent one.

A Manager can preview a conflict-free candidate list for any plan before committing, so "who's actually free" is answered before anyone gets double-booked by accident.

The shift lifecycle

This is where the plan meets the mop. Every day a Cleaning Plan is due, the system generates a **Shift** — a frozen, timestamped copy of that day's rooms, tasks, and assigned crew. It is the single, permanent record of what actually happened that day, independent of whatever the underlying plan looks like later.

How a shift gets created

Shifts are generated automatically by a background process that checks every active plan on a regular cycle and creates the day's shift for anything due. Operations never wait on that clock, though: the instant a worker tries to check in, the system creates that day's shift on the spot if it doesn't already exist — so a plan created minutes ago, or a missed scheduling cycle, never blocks someone standing on site ready to work.

Status: upcoming → in progress → completed

Two transitions, both automatic: the first check-in starts the shift, and finishing every task closes it — no manual "start" or "finish" button either side has to remember.

Checking in — proving the worker is actually there

A worker checks in by submitting their phone's GPS location. The system measures the distance to the Location's recorded coordinate and rejects the check-in — showing exactly how far off they are — if it's more than **50 metres** away. The first successful check-in on a shift is also what moves its status to *In Progress*.

Working the checklist

Every task on a shift is closed out one of two ways:

Photo-proof tasks. The worker uploads the required photos. The task completes itself automatically the instant every required photo for that visit is in.

Simple tasks. No photo required — the worker marks it done directly. This one is deliberately never automatic; a person has to confirm it.

The moment every task on the shift is done, the whole shift automatically flips to **Completed**.

Checking out

A worker cannot check out until the shift is fully **Completed** — every task done first. Check-out is GPS-verified the same way check-in is, and the moment it's recorded, the system logs the exact hours worked for that visit.

Live progress

Both the crew and the client's dashboard see the same numbers as the shift is worked: percentage complete per room, and an overall percentage averaged evenly across every room — so one large room full of tasks can't quietly dominate the number and hide slow progress everywhere else.

Ad-hoc task requests

Sometimes the job changes on the day — a spill, a one-off deep clean, a client asking for "one more thing." That is an **Additional Task**, handled on its own small approval flow rather than editing the recurring schedule itself.

1 Request is raised

A Client asks for an extra task on a specific date against one of their plans — it starts as **Pending**. If a Manager raises it directly instead, it is approved automatically on the spot.

CLIENT OR MANAGER

2 Manager reviews it

Approve — optionally adjusting the duration or exact requirements first — or reject with a stated reason.

MANAGER

3 It lands on today's shift immediately

An approved task is folded straight into that day's shift the moment it's approved, so the crew doesn't wait for the next scheduling cycle to see it.

SYSTEM

Managers run the business from a set of live and historical views, all built from the same underlying shift and plan data described above.

- **Today's board** — every shift happening today, broken down by status (upcoming / in progress / completed), plus how many workers are currently running late.
- **Trend reports** — shift volume over the past week, month, quarter, or year, for spotting patterns at a glance.
- **Attendance & performance** — per worker: hours worked, on-time percentage, late arrivals and absences, for today, this week, or this month.
- **Full roster** — a day, week, or month grid showing every worker's shifts across every client at once, the master view of who's working where.

Late means checked in after the shift's scheduled start time.

Absent means the shift's date has already passed with no check-in at all.
